Excellent content can still be hard to use when a learner cannot name the skill they are missing. Searching the broad topic may lead to a whole lesson, while the immediate problem is one earlier step, such as turning factors into solutions. For learners studying in short windows, choosing the right help is part of the problem.

The navigation problem matters when secondary mathematics learners return to a classroom or self-study goal: they need useful review without repeating everything underneath it. A teacher also needs a manageable way to support different gaps while keeping the class working toward a shared lesson.

The proposed school work starts with teacher-confirmed destinations and recurring access to devices and Khan Academy. We will record learners excluded or delayed by connectivity rather than assuming universal access. Learners needing support beyond the route will be referred to an educator.

Local validation remains a priority before implementation. We plan permitted walkthroughs with 10–15 learners and interviews with 3–5 teachers to examine recent experiences, existing workarounds, incorrect prerequisite assumptions, acceptable teacher effort, and realistic schedules. The findings will guide the first school cycle.

The central need to validate is specific: whether learners and educators would benefit from a clearer route between current difficulty, relevant Khan practice, and successful return to today's task. Findings will determine which destinations and school routines enter the pilot.
