The unit of replication is a destination kit: a current learning goal, reviewed prerequisite map, discriminating checks, matched Khan materials, parallel return assessments, facilitator guide, and reporting definitions. A new educator should be able to use a kit without the student team designing individual rescue plans.

The initial mathematics destinations demonstrate the structure. Additional grades, courses, and self-study goals can enter through new reviewed kits. The five-month proof stays bounded while the product vision remains broad.

School adoption begins with one confirmed class destination and a recurring access window. We will test a second educator's use of a kit and record preparation, questions, and continuing support. Expansion depends on curriculum fit, usable evidence, access, and manageable teacher effort, not merely the ability to publish another webpage.

A separate public channel can bring learners through short mathematics videos, shared links, and QR codes directly to the relevant destination. We will measure the route into meaningful practice and return, not treat views as recovered learners. Public activity stays separate from the evaluated school cohort.

The current interface uses local state and requires no generative-model call. It still needs connectivity for initial loading and Khan material. Long-term scale will require accountable content review, maintenance, local implementation partners, and a tested continuation model. Educator review and a clear maintenance owner will accompany each new kit.
